(54) Title: CARRIER BODY FOR EXHAUST GAS CATALYSTS

## (57) Abstract

A metal catalyst carrier body includes layers of first and second metal sheets defining passages through which exhaust gases flow. The first metal sheet is corrugated and engaged with the second metal sheet in each of upstream and downstream regions at numeral contact points. In intermediate region between the upstream and downstream regions, the first metal sheet is out of engagement with the second metal sheet.

## DESCRIPTION

### CARRIER BODY FOR EXHAUST GAS CATALYSTS

#### Technical Field

5 The present invention relates to a carrier body for exhaust gas catalysts, and more particularly to a metal carrier body including wound, stacked or otherwise layered layers of high-temperature corrosion-proof metal sheets, which form a plurality of channels or passages through which exhaust gas  
10 can flow.

#### Background Art

15 Metal carrier bodies of this type are used, for example, in the exhaust gas systems of motor vehicles. These carrier bodies are exposed to severe alternating thermal stresses, which limit the service life thereof.

Various ways of increasing the elasticity of such carrier bodies and of controlling the compressive and tensile forces have been proposed. Japanese  
20 Published Non-Prosecuted Application JP-A 62-83044, corresponding to German Published Non-Prosecuted Application DE-A 35 34 904 discloses a catalyst carrier body which is made up of alternating layers of two dissimilar metal sheets consisting of a first metal  
25 sheet with double corrugations and a second metal sheet without any corrugation. In the carrier body of this type, the number of contact points between the two metal sheet decreases, thereby providing the required elasticity. Japanese Published Non-  
30 Prosecuted Application JP-A 6-269683 discloses a catalyst carrier body in which two dissimilar metal sheets forming alternating layers are a first metal sheet with a simple corrugation and a second metal

sheet without any corrugation, respectively. According to this known carrier body, at least one of the first and second metal sheets is formed with cutouts or openings. Alternatively, at least one of  
5 the first and second metal sheets is divided into a plurality of segments arranged in spaced relationships. In this carrier body, the cutouts or openings or spaces between the segments can control the compressive and tensile forces.

10 Carrier bodies are known which are wound from alternating layers of two differently corrugated metal sheets. One example is described in US-A 4,845,073 issued on Jul. 4, 1989 to Cyron. In this known carrier body, the metal sheets have inner and outer  
15 surfaces, and the contact points are disposed on the inner surface of the first metal sheet and on the outer surface of the second metal sheet. During winding, the inwardly oriented troughs are synchronized with inwardly oriented troughs of the  
20 second metal sheet.

An object of the present invention is to provide a carrier body for exhaust gas catalyst, which, with sufficiently high structural rigidity, has reduced mass to be heated as well as increased effective surface  
25 area exposed to exhaust gas.

#### **Disclosure of Invention**

According to one aspect of the present invention, there is provided a carrier body for exhaust gas catalysts, comprising:

30 layers of first and second metal sheets defining passages through which gas flows;

said layers having an upstream region and a downstream region, with respect to direction in which

gas flows, which are spaced from each other;

said layers having an intermediate region disposed between said upstream and downstream regions;

5       said first metal sheet being so corrugated as to be brought into contact with said second metal sheet in each of said upstream and downstream regions, said first corrugation;

10       said first metal sheet being out of contact with said second metal sheet in said intermediate region.

According to one specific aspect of the present invention, the second metal sheet is corrugated differently from the first corrugated metal sheet, and wherein the differently corrugated first and second  
15       metal sheets have periodicity permitting them to be synchronized with one after another in each of the upstream and downstream regions.

According to a further specific aspect of the present invention, only one of the differently  
20       corrugated first and second metal sheets extends in the intermediate region.

According to still further specific aspect of the present invention, the first metal sheet has a first corrugation with first periodicity and first amplitude,  
25       and the second metal sheet has a second corrugation with second periodicity and second amplitude. The first periodicity is substantially equal to the second periodicity and the second amplitude is less than the first amplitude. Only one of the first and second  
30       metal sheets extends in the intermediate region.

According to another specific aspect of the present invention, in each of the upstream and downstream regions, the first metal sheet has a first

corrugation with first periodicity and first amplitude, and, in the intermediate region, the first metal sheet has a second corrugation with second periodicity and second amplitude that is less than the first amplitude.

### 15 **Best Mode for Carrying Out the Invention**

Referring to the drawings and particularly to Fig. 1, exhaust gas from an internal combustion engine is supplied in the direction of an arrow 10 to an exhaust gas converter 12. The exhaust gas converter 12 has a shell-like housing 14. The housing 14 has at one longitudinal end thereof an inlet 16 and at the opposite longitudinal end thereof an outlet 18. A carrier body 20 for exhaust gas catalyst has a support 22, and it is mounted in the housing 14. The carrier body 20 may be divided into and consists of three regions, namely, an upstream region 30, a downstream region 32, and an intermediate region 34 between the upstream and downstream region 30 and 32.

30 Fig. 2 shows the exhaust passages 36 in the upstream region 30, and Fig. 4 is an enlarged fragmentary view thereof. The downstream region 32 is identical in construction to the upstream region 30.

Fig. 3 shows the exhaust passages 38 in the intermediate region 34, and Fig. 5 is an enlarged fragmentary view thereof. In each of the upstream and downstream regions, the carrier body 20 includes stacked alternating layers of two different corrugated metal sheets, namely, a first metal sheet 40 and a second metal sheet 42. In the intermediate region 34, the carrier body 20 includes spaced layers of one of the two different corrugated metal sheets 40 and 42.

The two corrugated metal sheets 40 and 42 have periodicity permitting them to be synchronized with one another when they are stacked. The result is a very uniform distribution of contact points, which have shapes that adapt to one another and an identical direction of curvature between the two metal sheets 40 and 42.

Viewing in Fig. 4, the first metal sheet 40 has upper and lower surfaces 44 and 46, and the second metal sheet 42 has upper and lower surfaces 48 and 50. The contact points may be divided into a first group and a second group. The contact points of the first group are disposed on the lower surface 46 of the first sheet metal 40 and on the upper surface 48 of the second sheet metal 42. In other words, the downwardly oriented troughs of the corrugation of the first metal sheet 40 are synchronized with the downwardly oriented troughs of the corrugation of the second metal sheet 42 during stacking the metal sheets 40 and 42 one after another. The contact points of the second group are disposed on the upper surface 44 of the first metal sheet 40 and on the lower surface 50 of the second metal sheet 42. In

other words, the upwardly oriented crests of the corrugation of the first metal sheet 40 are synchronized with the upwardly oriented crests of the corrugation of the second metal sheet 42 during  
5 stacking the metal sheets 40 and 42 one after another.

In this example, the first metal sheet 40 extend through the whole lengths, in the longitudinal direction of the carrier body 20, of the upstream  
10 region 30, intermediate region 34 and downstream region 32. The second metal sheet 42 extends through the whole length of the upstream region 30 and that of the downstream region 32 only. In other words, the second metal sheet 42 does not extend  
15 through the intermediate region 34 as seen from Figs. 3 and 5.

The corrugation of the first metal sheet 40 has a periodicity  $P_1$  and amplitude  $A_1$ , while the corrugation of the second metal sheet 42 has a  
20 periodicity  $P_2$  and amplitude  $A_2$ .  $P_2$  is substantially the same as  $P_1$  and  $A_2$  is sufficiently smaller than  $A_1$  to cause the curvature of the first metal sheet 40 at the contact points to be somewhat greater than the curvature of the second metal sheet 42 at the contact  
25 points.

Preferably,  $P_1 = P_2$ ,  $A_1 = nP_1$  and  $A_1 = mA_2$ , where:  $n$  ranges from 0.2 to 0.3, and  $m$  ranges from 2.4 to 6.

In this example, the corrugations are substantially sinusoidal. The waveform is a sine-  
30 wave form. The first metal sheet 40 has the wave height  $2A_1$  (twice the wave amplitude  $A_1$ ) of 1.2 mm and the wavelength  $P_1$  ranging from 2.0 mm to 3.0 mm. The second metal sheet 42 has the wave height

2A2 (twice the wave amplitude A2) ranging from 0.2 mm to 0.5 mm and the wavelength P2 substantially equal to P1.

Due to the fact that P1 is substantially equal to  
5 P2, the crests and troughs of the stacked layers of the first metal sheet 40 are aligned in the longitudinal direction through the whole length of the intermediate region 34. In the intermediate region 34, the cross sections of the passages 38 that are  
10 particularly narrow or wide are not produced. This is advantageous upon subsequent coating of the carrier body 20 with the catalyst material. This is because small gaps that become plugged are not produced.

Thus, in the intermediate region 34, the first  
15 metal sheet 40 has sufficiently wide effective surface area, i.e., the surface area of catalyst coating layer, that can contact with exhaust gases. This can minimize waste in catalyst coating.

Besides, it is assured that the exhaust gases  
20 contact sufficiently with the catalyst coating, resulting in increased conversion efficiency of the catalyst.

During a cold start, the catalyst of the exhaust gas converter 12 is below its start-up temperature  
25 and must be brought to its operating temperature by the exhaust gases of the engine. The smaller the mass of catalyst to be heated, the quicker it will reach its start-up temperature. In the intermediate region 34 of the carrier body 20, the second metal  
30 sheet 42 is not employed, causing a reduction in the mass to be heated. The result is a reduction in time required for the catalyst to reach its start-up temperature.

## 9

In the intermediate region 34 of the carrier body 20, the stacked layers of the first metal sheet 40 can be condensed without producing any local narrow gaps that might become plugged because the crests and troughs are held aligned in the longitudinal direction of the carrier body 20. This is advantageous in increasing the effective surface area of the catalyst coating that becomes exposed to the exhaust gases.

Referring to Fig. 4, the distance H between the adjacent layers of the first metal sheet 40 can be narrowed by using layers of the second metal sheet 42 with increased amplitude A2.

In the previously described embodiment, the second metal sheet 42 has been removed in the intermediate region 34. Alternatively, the first metal sheet 40 may be removed in the intermediate region 34 of the carrier body 20.

According to the first embodiment, the carrier body 20 is made up of stacked layers of two dissimilar or differently corrugated metal sheets 40 and 42. However, the present invention may be embodied in a carrier body including wound layers of the dissimilar corrugated metal sheets 40 and 42.

In the first embodiment of the carrier body 20, there exists no contact point between the first and second metal sheets 40 and 42 in the intermediate region 34 due to the removal of the second metal sheet 42.

In the second embodiment to be described below, a double corrugated metal sheet is used as the first metal sheet. The double corrugated metal sheet includes, in addition to a first corrugation, a second

corrugation with amplitude smaller than amplitude of the first corrugation. In each of upstream and downstream regions of a carrier body, the first corrugation makes contact with layers of the second metal sheet. In the intermediate region, the second corrugation is disposed in spaced relation with the second metal sheets. In other words, there exists no contact point in the intermediate region.

Referring to Figs. 6 to 13, the second embodiment of a carrier body 60 is described.

Fig. 6 shows, in diagram, a partial plan view of the carrier body 60 in which an arrow 10 indicates the direction of exhaust gases from an internal combustion engine supplied to the carrier body 60. The carrier body 60 may be divided into and consists of five regions, namely an upstream region 62, a first transition region 64, an intermediate region 66, a second transition region 68 and a downstream region 70. Fig. 7 shows the exhaust passages 72 in the upstream region 62. Fig. 8 shows the exhaust passages 74 in the first transition region 64. Fig. 9 shows the exhaust passages 76 in the intermediate region 66. Fig. 10 shows the exhaust passages 78 in the second transition region 68. Fig. 11 shows the exhaust passages 80 in the downstream region 70.

In each of these regions 62, 64, 66, 68 and 70, the carrier body 60 includes stacked alternating layers of a first metal sheet 82 and a second metal sheet 84. In this example, the first metal sheet 82 has double corrugations, and the second metal sheet 84 is a smooth flat sheet. Alternatively, the second metal sheet 84 may have a sinusoidal waveform. As different from the first embodiment, the second metal

## 11

sheet 84 extend through the whole lengths of the first transition region 64, intermediate region 66 and second transition region 68.

Viewing in Figs. 7 through 11, the first metal  
5 sheet 82 has upper and lower surfaces 86 and 88, and the second metal sheet 84 has upper and lower surfaces 90 and 92. The first and second metal sheets 82 and 84 are stacked one after another. The result is a uniform distribution of a great number of  
10 contact points in each of the upstream and downstream regions 62 and 72 (see Fig. 7 and 11). There occurs a uniform distribution of reduced number of contact points in each of the first and second transition regions 64 and 70 (see Figs. 8 and  
15 10). In the intermediate region (see Fig. 9), there is no contact point. The contact points may be divided into a first group and a second group. The contact points of the first group are disposed on the lower surface 88 of the first metal sheet 82 and on the  
20 upper surface 90 of the second metal sheet 84. In other words, the downwardly oriented troughs of a first one 94 of the double corrugations of the first metal sheet 82 are brought into contact with the upper surface 90 of the second metal sheet 84 during  
25 stacking the metal sheets 82 and 84 one after another. The contact points of the second group are disposed on the upper surface 86 of the first metal sheet 82 and on the lower surface 92 of the second metal sheet 84. In other words, the upwardly  
30 oriented crests of the first one corrugation 94 of the first metal sheet 82 are brought into contact with the lower surface 92 of the second metal sheet 84 during stacking the metal sheets 82 and 84.

The first metal sheet 82 has, in addition to the first corrugation 94, a second corrugation 96. The first corrugation 94 has a periodicity  $P3$  and amplitude  $A3$ . The second corrugation 96 has a  
5 periodicity  $P4$  and amplitude  $A4$ .  $A4$  is smaller than  $A3$  and  $P4$  is expressed by the formula:

$$P4 = P3 \times (1/N)$$

where:  $N \geq 2$  ( $N$  is the integer).

In this example,  $N$  is 2 and thus  $P4 = P3 \times (1/2)$   
10 holds. Since, in this example, the corrugations 94 and 96 are substantially sinusoidal and the waveform is a sine-wave form, two small waves of the second corrugation 96 has replaced one big wave of the first corrugation 94.

15 Turning back to Fig. 6, the first corrugation 94 extends through each of portions indicated by shadowed area, while the second corrugation 96 extends through each of void portions. In Figs. 8, 9 and 10, the dashed line illustrates the first  
20 corrugation 94, which extends through the upstream portion 62.

In the first transition region 64 shown in Fig. 8, two small waves of the second corrugation 96 have replaced every other one of the big waves of the first  
25 corrugation 94 as re. In the intermediate region 66 shown in Fig. 9, two small waves of the second corrugation 96 have replaced the other big waves of the first corrugation 94. In the second transition region 68 shown in Fig. 10, every other one of the big  
30 waves of the first corrugation 94 which has been replaced by the two small waves of the second corrugation 96 in the first transition region 64 reinstates as shown in Fig. 12. In the downstream

region 70 shown in Fig 11, all of the big waves of the first corrugation 94 reinstate.

Along the boundary between the upstream and first transition regions 62 and 64, cutting every other  
5 one of the big waves of the first corrugation 94 from a point c to a point permits two small waves of the second corrugation 96 to be formed as shown in Fig. 12. Along the boundary between the first transition and intermediate regions 64 and 66, cutting each of  
10 the remaining big waves of the first corrugation 94 from a point d to a point e permits two small waves of the second corrugation 96 to be formed as shown in Fig. 13.

In a similar manner, the small waves of the  
15 second corrugation 96 in the second transition region 70 are formed.

In the carrier body 60, the small waves of the second corrugation 96 have replaced most of the big waves of the first corrugation 94 in the first  
20 transition region 64, intermediate region 66 and second transition region 68. The result is a considerable reduction in number of the contact points between the first and second metal sheets 82 and 84. This is advantageous upon subsequent  
25 coating of the carrier body 60 with the catalyst material.

In the upstream and downstream regions 62 and 70, the double corrugated first metal sheet 82 is fixedly secured to the adjacent two layers of the  
30 second metal sheet 84. This is effective for the metal sheet 82 to maintain its originally designed shape. The results in an increased structural strength of the carrier body 60, making it possible to

## 14

extend its service life.

As explained before, every other one of big waves of the first corrugation 94 turns into two small waves of the second corrugation 96 at the boundary between the second transition region 68. The result is an increased integrality between the first corrugation 94 and the second corrugation 96.

The relation that  $P4 = P3 \times (1/N)$  holds, where: N is the integer and not less than 2. This is advantageous in forming the small waves of the second corrugation 96 in each of the first and second transition regions 64 and 68. This is because the big waves of the first corrugation 94 and the small waves of the second corrugation 96 are bridged smoothly and continuously. As a result, the productivity as well as the structural strength is enhanced.

In the second embodiment of the carrier body 60, the intermediate region 66, where only the small waves of the second corrugation 96 exist between the adjacent two layers of the second metal sheet 84, is disposed between the upstream and downstream regions 62 and 70. In other words, the big wave-dominating region 62, the small wave-dominating region 66 and the big wave-dominating region 70 are arranged in the direction of exhaust gases passing through the carrier body 60. This arrangement may be cyclically repeated in the direction of exhaust gases. This cyclical arrangement is advantageous in increasing the diffusion of the exhaust gases passing through the carrier body. This results in increased conversion efficiency of the catalyst. This arrangement provides increased distribution of contact points in the direction of exhaust gases and

thus over the length and width of the carrier body, thus providing increased structural strength of the carrier body.

Referring to Figs. 14 to 19, the third embodiment  
5 of a carrier body 60A is described.

The carrier body 60A is substantially the same as the carrier body 60 just described as the second embodiment. However, it is different in that big waves of first corrugation 94 in downstream region  
10 70A are out of phase of big waves of the first corrugation 94 in upstream region 62. In second transition region 68A (see Fig. 18) of the carrier body 60A, two small waves of second corrugation 96 have replaced every other one of the big waves in the  
15 downstream region 70A (see Fig. 19).

This phase-shift provides further increased diffusion of exhaust gases passing through the carrier body 60A. As a result, the conversion efficiency of catalyst is increased further.

**CLAIMS**

- 1 1. A carrier body for exhaust gas catalysts,  
2 comprising:  
3 layers of first and second metal sheets defining  
4 passages through which gas flows;  
5 said layers having an upstream region and a  
6 downstream region, with respect to direction in which  
7 gas flows, which are spaced from each other;  
8 said layers having an intermediate region  
9 disposed between said upstream and downstream  
10 regions;  
11 said first metal sheet being so corrugated as to  
12 be brought into contact with said second metal sheet  
13 in each of said upstream and downstream regions,  
14 said first corrugation;  
15 said first metal sheet being out of contact with  
16 said second metal sheet in said intermediate region.
- 1 2. A carrier body as claimed in claim 1, wherein said  
2 second metal sheet is corrugated differently from said  
3 first corrugated metal sheet, and wherein said  
4 differently corrugated first and second metal sheets  
5 have periodicity permitting them to be synchronized  
6 with one after another in each of said upstream and  
7 downstream regions.
- 1 3. A carrier body as claimed in claim 2, wherein only  
2 one of said differently corrugated first and second  
3 metal sheets extends in said intermediate region.
- 1 4. A carrier body as claimed in claim 1, wherein said  
2 first metal sheet has a first corrugation with first

3 periodicity and first amplitude, and said second metal  
4 sheet has a second corrugation with second  
5 periodicity and second amplitude;

6 wherein said first periodicity is substantially  
7 equal to said second periodicity and said second  
8 amplitude is less than said first amplitude; and

9 wherein only one of said first and second metal  
10 sheets extends in said intermediate region.

1 5. A carrier body as claimed in claim 4, wherein said  
2 upstream and downstream regions include one and  
3 opposite ends between which said layers extend,  
4 respectively.

1 6. A carrier body as claimed in claim 4, wherein, in  
2 each of said upstream and downstream portions, the  
3 adjacent two layers of said corrugated first metal  
4 sheet are spaced from each other by one layer of said  
5 corrugated second metal sheet; and wherein said  
6 second amplitude defines spacing between said the  
7 adjacent two layers of said corrugated first metal  
8 sheet.

1 7. A carrier body as claimed in claim 1, wherein the  
2 adjacent two layers of said second metal sheet are  
3 engaged with the adjacent two layers of said first  
4 metal sheet for positioning between said the adjacent  
5 two layers of said first metal sheet.

1 8. A carrier body as claimed in claim 4, wherein  
2  $P1 = P2$ ;  
3  $A1 = nP1$ ; and  
4  $A1 = mA2$ ,

5       where:    n ranges from 0.2 to 0.3,  
6                m ranges from 2.4 to 6,  
7                P1 is the first periodicity,  
8                P2 is the second periodicity,  
9                A1 is the first amplitude, and  
10               A2 is the second amplitude.

1    9. A carrier body as claimed in claim 1, wherein, in  
2    each of said upstream and downstream regions, said  
3    first metal sheet has a first corrugation with first  
4    periodicity and first amplitude; and wherein, in said  
5    intermediate region, said first metal sheet has a  
6    second corrugation with second periodicity and  
7    second amplitude that is less than said first  
8    amplitude.

1    10. A carrier body as claimed in claim 9, wherein, in  
2    said intermediate region, said second corrugation  
3    extends through the whole area of said first metal  
4    sheet.

1    11. A carrier body as claimed in claim 9, wherein said  
2    upstream region, said intermediate region and said  
3    downstream region are arranged in this order  
4    cyclically.

1    12. A carrier body as claimed in claim 9, wherein,  
2    said layers have a first transition region between said  
3    upstream region and said intermediate region and a  
4    second transition region between said intermediate  
5    region and said downstream region.

1    13. A carrier body as claimed in claim 12, wherein, in

2 each of said first and second transition regions, said  
3 first corrugation and said second corrugation coexist.

1 14. A carrier body as claimed in claim 9, wherein  
2  $P4 = P3 \times (1/N)$   
3 where:  $N \geq 2$  and an integer,  
4  $P3$  is the first periodicity, and  
5  $P4$  is the second periodicity.

1 15. A carrier body as claimed in claim 9, wherein said  
2 first corrugation in said downstream region is out of  
3 phase with that in said upstream region.

1 16. A carrier body as claimed in claim 13, wherein  
2 said second metal sheet is a generally smooth flat  
3 sheet, wherein said first metal sheet is engaged with  
4 said second metal sheet at first contact points in each  
5 of said upstream and downstream regions, and  
6 wherein said first metal sheet is engaged with said  
7 second metal sheet at second contact points that are  
8 less in number than said first contact points.

## INTERNATIONAL SEARCH REPORT

Int. nat. Application No.

PCT/JP 97/01802

A. CLASSIFICATION OF SUBJECT MATTER  
IPC 6 B01J35/04

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)  
IPC 6 B01J

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
P,X	US 5 567 395 A (OKABE SHINICHI ET AL) 22 October 1996 see figures 1-3 see column 2, line 36 - column 3, line 37 see claim 1	1
Y	---	2-7
Y	EP 0 389 750 A (BEHR GMBH & CO) 3 October 1990 see figure 2 see column 3, line 58 - column 4, line 33	2-7

	--- -/--	

☒ Further documents are listed in the continuation of box C.☒ Patent family members are listed in annex.

## \* Special categories of cited documents:

\*A\* document defining the general state of the art which is not considered to be of particular relevance

\*E\* earlier document but published on or after the international filing date

\*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

\*O\* document referring to an oral disclosure, use, exhibition or other means

\*P\* document published prior to the international filing date but later than the priority date claimed

\*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

\*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

\*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

\*&amp;\* document member of the same patent family

Date of the actual completion of the international search

22 September 1997

Date of mailing of the international search report

29.09.97
